🔷 Title

Near-Universal 1:1 Balance in Sangbun Vector Geometry

🔷 Description

This note reports a consistent numerical observation in Sangbun vector geometry.

For a wide class of functions f, including both linear and nonlinear cases, the total lengths of the

projection component (AA6) and the rotational component (AA11) satisfy:
錍 \sum |AA6| \approx \sum |AA11|. 錍
For linear functions, this balance appears to be exact, while for nonlinear curves it is approximately preserved.
These results suggest that Sangbun vector geometry possesses an inherent

balance structure between projection and rotation components, which remains stable even under curvature.
This observation may indicate a deeper structural principle underlying the construction of the Sangbun vector.
